This is a PDF file of an unedited manuscript that has been accepted for publication. As a service to our customers we are providing this early version of the manuscript. The manuscript will undergo copyediting, typesetting, and review of the resulting proof before it is published in its final form. Please note that during the production process errors may be discovered which could affect the content, and all legal disclaimers that apply to the journal pertain.

Highlights

- The full-length genome of canine coronavirus type I was determined
- Sequence analysis showed unique features with respect to canine coronavirus type II
- By phylogeny, canine coronavirus type I formed a separate cluster
- The results may contribute to the understanding of the *Alphacoronavirus-1* evolution

Full-length genome analysis of canine coronavirus type I

1 **Abstract**

2 Canine coronavirus types I (CCoV-I) and II (CCoV-II) are usually responsible for mild enteritis in
3 dogs. While the CCoV-II genome has been completely sequenced, to date there are no complete
4 genomic sequence data available publicly for CCoV-I. Thus, the aim of the present study was to
5 analyse the full-length genome of a CCoV-I prototype strain that had been recovered from a dog
6 with diarrhea in Italy. CCoV-I strain 23/03 has a genome of 30,000 nucleotides, excluding the 3'
7 poly(A) tail, displaying the typical *Alphacoronavirus-1* organization and the highest genetic
8 relatedness to CCoV-II. However, two distinct features were observed in the CCoV-I genome: i) the
9 presence of an additional ORF between the spike (S) protein gene and ORF3a; ii) the diversity of
10 the S protein, which is more closely related to that of feline coronavirus type I and presents a furin
11 cleavage site. The present study may contribute to a better understanding of the *Alphacoronavirus-1*
12 evolutionary pattern and may be paradigmatic of how coronaviruses evolve through gene losses,
13 acquisition and exchanges among different members.

1. Introduction

Coronaviruses (CoVs) are large, single-stranded, positive-sense RNA viruses, which are responsible for enteric and/or respiratory disease in mammals and birds. Canine coronavirus (CCoV) is usually responsible for mild enteritis in young dogs [Decaro and Buonavoglia, 2008, 2011], although fatal disease has been associated to a pantropic variant of the virus [Decaro et al., 2008, 2010a, 2012; Marinaro et al., 2010; Zicola et al., 2012; Ntafis et al., 2012]. Based on the genetic distance encountered in the spike (S) protein gene [Pratelli et al., 2003], two CCoV genotypes are known, CCoV type I (CCoV-I) and type II (CCoV-II), which are variously distributed worldwide [Decaro et al., 2005, 2011, 2013; McElligot et al., 2011; Soma et al., 2011; Ntafis et al., 2013; Licitra et al., 2014; Cavalli et al., 2014; Costa et al., 2014]. CCoV-II has been found to exist in two different subtypes, CCoV-IIa and CCoV-IIb, the latter being the result of homologous recombination with transmissible gastroenteritis virus of swine (TGEV) [Decaro et al., 2009, 2010b]. Intermediate viruses between CCoV-I and CCoV-II have been also detected [Town and Whittaker, 2012].

CCoV-I and CCoV-II form a unique viral species, *Alphacoronavirus-1* (family *Coronaviridae*, genus *Alphacoronavirus*), along with feline coronavirus types I (FCoV-I) and II (FCoV-II), TGEV and porcine respiratory coronavirus (PRCoV) [Decaro and Buonavoglia, 2011]. An additional ORF, named ORF3, was found in the CCoV-I genome, whereas only its remnants were evident in the genomes of CCoV-II and TGEV, revealing an intriguing evolutionary history within the *Alphacoronavirus-1* species [Lorusso et al., 2008].

While the full-length genomes of several strains of CCoV-II have been determined [Decaro et al., 2015], to date there are no complete genomic sequence data available publicly for CCoV-I. Thus, the aim of the present study was to analyse the full-length genome of a CCoV-I prototype strain that had been recovered from a dog with diarrhea in Italy.

2. Materials and methods

1 **2.1. Virus origin**

2 Strain 23/03 was detected during an epidemiological survey for CCoV in Italian dogs with diarrhea
 3 [Pratelli et al., 2004]. The ill dog, a male German shepherd of 6 weeks of age, belonged to a kennel
 4 located in the Apulia region, southern Italy. The feces were collected by a vet directly from the
 5 rectal ampulla into a sterile container during the clinical examination of the dog. CCoV-I RNA
 6 detection in the specimen was obtained by means of genotype-specific PCR [Pratelli et al., 2004]
 7 and real-time RT-PCR [Decaro et al., 2005]. Virus isolation attempts using different cell lines of
 8 canine and feline origin were unsuccessful, since CCoV-I has not been adapted to the *in-vitro*
 9 growth [Decaro and Buonavoglia, 2008, 2011]. The original fecal sample was aliquoted and stored
 10 at -70°C until RNA extraction.

12 **2.2. RNA extraction**

13 An aliquot of the original fecal specimen was clarified by centrifuging at 2,500 x g for 10 min. One-
 14 hundred-forty microliters of the supernatant were then used for RNA extraction by means of
 15 QIAamp® Viral RNA Mini Kit (Qiagen S.p.A., Milan, Italy), following the manufacturer's protocol
 16 and the RNA template was stored at -70°C until its use.

18 **2.3. CCoV detection, quantification and characterization**

19 The RNA extract was subjected to a previously-established TaqMan-based real-time RT-PCR assay
 20 for rapid detection and quantification of CCoV RNA [Decaro et al., 2004], with minor
 21 modifications. Briefly, a one-step method was adopted using SuperScript® III Platinum® One-Step
 22 qRT-PCR Kit (Life Technologies srl, Milan, Italy) and the following 50-µl mixture: 25 µl of master
 23 mix, 1 µl of SuperScript® III RT/Platinum Taq Mix, 300 nM of primers CCoV-For and CCoV-Rev,
 24 200 nM of probe CCoV-Pb [Decaro et al., 2004] and 10 µl of template RNA. Duplicates of log₁₀
 25 dilutions of standard RNA were analyzed simultaneously in order to obtain a standard curve for
 26 absolute quantification. The thermal profile consisted of reverse transcription at 50°C for 15 min

and activation of Platinum Taq DNA polymerase at 95° C for 2 min, followed by 45 cycles of denaturation at 95° C for 15 s, annealing at 48° C for 30 s and extension at 60° C for 30 s. CCoV genotyping was achieved by means of two distinct genotype-specific assays [Decaro et al., 2005] performed by using SuperScript® III Platinum® One-Step qRT-PCR Kit (Life Technologies srl) and the following oligonucleotide sets (final concentrations were 600 and 200 nM for primers and probes, respectively): primer pair CCoV-F/CCoV-R and probe CCoV-Pb for CCoV-I and CCoV-F/CCoV-R and probe CCoV-Pb [Decaro et al., 2005] for CCoV-II. The thermal protocol was as described for CCoV detection except for different annealing temperatures (53°C and 48°C for CCoV-I and CCoV-II, respectively).

2.4. RT-PCR amplifications

Overlapping fragments of the genome of CCoV-I strain 23/03 were obtained through RT-PCR reaction carried out using primer sets designed based on the genome sequence of other alphacoronaviruses and the kit SuperScript™ One-Step RT-PCR for Long Templates (Life Technologies srl). Additional RT-PCR assays and subsequent sequencing attempts were performed to close gaps between assembled contigs and to sequence unresolved genomic regions using primers designed on the alignment of the reference *Alphacoronavirus* strains. The very 5' and 3' ends were amplified using 5' and 3' RACE System for Rapid Amplification of cDNA Ends (Invitrogen), respectively, following the manufacturer's instructions. The PCR products were detected by electrophoresis through a 1.5% agarose gel and visualisation under UV light after ethidium bromide staining.

2.5. Sequence analysis and phylogeny

RT-PCR products were subjected to direct sequencing at the BaseClear B.V. (Leiden, The Netherlands). The sequences were manually edited and analyzed using the Geneious platform (<http://www.geneious.com>) and the NCBI's (<http://www.ncbi.nlm.nih.gov>) and EMBL's

(<http://www.ebi.ac.uk>) analysis tools. Nucleotide (nt) sequences of the different ORFs were converted into amino acid (aa) sequences and comparative sequence analysis with reference coronavirus sequences was carried out in the full-length genome and encoded structural and nonstructural proteins.

Phylogenetic and molecular evolutionary analyses were conducted using Mega4.1 Beta [Tamura et al., 2007]. In order to include in the analysis CCoV-IIb, whose genome has not been completely sequenced, phylogenetic trees were elaborated on a 22,366 genomic sequence (encompassing from the 3' end of ORF 1a to the 3' UTR) and on the amino acid (aa) sequences of S, membrane (M), and nucleocapsid (N) proteins using both parsimony and neighbor-joining methods, supplying a statistical support with bootstrapping over 1000 replicates. The following *Alphacoronavirus* reference strains were used for phylogeny (GenBank accession numbers are indicated in parentheses): CCoV-IIa 1/71 (JQ404409), K378 (KC175340), S378 (KC175341), TN449 (JQ404410), NTU366/F/2008 (GQ477367), CB/05 (KP981644); CCoV-IIb 174/06 (EU856362), 341/05 (EU856361); CCoV A76 (JN856008); FCoV-I Black (EU186072); FCoV-II 79-1146 (DQ010921), 79-1683 (JN634064); TGEV Purdue (DQ811789); PRCoV ISU-1 (DQ811787). The distantly-related *Betacoronavirus-1* canine respiratory coronavirus (CRCoV) K37 (JX860640) was used as outgroup.

2.6. Nucleotide sequence accession number

The full-length genome of CCoV-I strain 23/03 was deposited in GenBank under accession number KP849472.

3. Results

3.1. Detection of CCoV-I

By the real-time RT-PCR panels, the fecal sample was confirmed to contain a CCoV-I strain, whose titer was calculated as 6.73×10^6 RNA copies/ μ L of template. The specimen had no traces of CCoV-II RNA.

3.2. CCoV-I genomic organization

The genome of CCoV-I strain 23/03 has a size of 30,000 nt, excluding the 3' poly(A) tail, and shows typical *Alphacoronavirus-1* organization (Table 1 and Fig. 1). The 5' UTR consists of 313 nt including the leader sequence (L, nt 1 to 94) and the conserved core 5'-CUAAAC-3' (nt 95 to 100) of the transcription regulatory sequence (TRS), which controls the mRNA synthesis through interaction with the viral polymerase during the discontinuous transcription of the negative strand subgenomic RNA of the *Nidovirales* members [Enjuanes et al., 1991]. Similar TRS signals precede each of the 8 putative mRNA encoding for the structural and nonstructural proteins (Table 1). The 3' end of the viral genome consists of a 274-nt 3' UTR that is followed by the poly(A) tail. Sequence analysis showed intact structural and non-structural proteins with respect to reference CCoV-II, FCoV-I and FCoV-II genomes. About two-thirds of the viral genome is occupied by the replicase gene and encoding for two large polyprotein (pp), pp1a and pp1ab, the latter being synthesised through ribosomal slippage at position 12,327. The polyproteins of the replicase complex are processed by viral proteinases, resulting in several products with different size and function. Sequence comparison with other *Alphacoronavirus-1* genomes led to the detection of three putative papain-like proteinase cleavage sites and 11 putative 3C-like proteinase cleavage sites, producing 16 nonstructural proteins (Table 2).

Four structural proteins were detected downstream of the replicase gene, namely the spike (S), small envelope (E), membrane (M) and nucleocapsid (N) proteins. The S protein has a size of 1481 aa, thus being longer than the analogous protein of other *Alphacoronavirus-1* members (1451-1457 aa in CCoV-II and FCoV-II, 1457-1464 aa in FCoV-I, 1447-1449 aa in TGEV, 1225 aa in PRCoV). By using the NetNGlyc server (<http://www.cbs.dtu.dk/services/NetNGlyc/>), 28 N-glycosylation

1 sites were predicted in the CCoV-I 23/03 S protein, whereas 30-33 *N*-glycosylated Asn residues had
2 been detected in CCoV-II [Sanchez et al., 1999; Decaro et al., 2007]. At position 802-806, the S
3 protein exhibits a potential cleavage site, represented by the basic aa stretch Arg-Arg-Val-Arg-Arg
4 (RRVRR). This stretch had been also observed in the sequence of the S protein of Elmo/02
5 (position 801-805), but in this strain an Ala residue has replaced Val at position 803 [Pratelli et al.,
6 2003]. With few exceptions [de Haan et al., 2008], other alphacoronaviruses do not share this
7 finding.

8 The E protein is 82-aa long and does not present any *N*-glycosylation sites, whereas three *N*-
9 glycosylated residues have been detected in the 264-aa long M protein, which is in agreement with
10 what has been observed in other FCoV/CCoV strains, with the exception of CCoV-II isolate BGF10
11 that shows only two glycosylated Asn residues [Sanchez et al., 1999]. The N protein of strain
12 CCoV-I 23/03 is 380-aa long product with three potential *N*-glycosylation sites.

13 Analogously to CCoV-II and FCoV-I/II, some accessory genes were detected between ORFs 2 (S-
14 protein gene) and 4 (E-protein gene) and downstream of ORF6 (N-protein gene). The S-E
15 intergenic region contains the canonical three ORFs 3a, 3b and 3c, encoding for products with sizes
16 of 78, 71 and 251 aa, respectively, plus an additional accessory protein gene, ORF3, encoding for a
17 putative 206 aa protein, which has been found to be unique to the CCoV-I genome [Lorusso et al.,
18 2008]. The 3' end accessory genes were ORFs 7a and 7b that encoded for 101-aa and 213-aa long
19 proteins, respectively.

21 3.3. Sequence analysis

22 Alignment of complete genome sequences of CCoV-I strain 23/03 and reference
23 alphacoronaviruses showed the closest genetic relatedness with CCoV-IIa isolates (83.82-84.98% nt
24 identity), followed by TGEV (82.81%) and FCoV (77.19-77.43%). No comparison was possible
25 with CCoV-IIb since there are no full-length genomes available in the GenBank database for this
26 virus. When the spike protein was analyzed, CCoV-I displayed a higher aa identity to FCoV-I

(73.09%) than to CCoV-IIa/IIb (42.74-43.71%), FCoV-II (43.05%) and TGEV (42.83%). Among extant CCoV strains, the closest identity was observed with isolate A76, which has been proven to have a CCoV-I/II recombinant S protein [Regan et al., 2012]. The E, M and N proteins of strain 23/03 were all more closely related to the analogous products of CCoV-II and porcine CoV reference strains (Table 3).

3.4. Phylogeny

In order to include in the analysis the nt sequences available for CCoV-IIb, phylogeny was first constructed on a 23,106-nt fragment spanning from the 3' end of ORF1a to the very 3' end of the viral genomes. In the neighbor-joining tree elaborated using these sequences, strain CCoV-I 23/03 clustered separately from extant CCoV/FCoV isolates leading to the formation of an outlier branch (Fig. 2A). The prototype CCoV-I strain formed a separate branch from other analysed alphacoronaviruses also in the trees elaborated using the M (Fig. 2C) and N (Fig. 2D) proteins, whereas the S protein revealed a clustering with FCoV-I (Fig. 2D). The same tree topologies were obtained through phylogenetic analysis using the maximum-parsimony method (data not shown).

4. Discussion

CCoV has progressively emerged as being responsible for moderate to severe enteritis in dogs, with different genotypes and subgenotypes being detected in recent years [Decaro and Buonavoglia, 2008, 2011]. CCoV-II is the oldest genotype, which has been known since 1971 [Binn et al., 1974], whereas CCoV-I was discovered only 30 years later thanks to molecular methods, since this virus has not been adapted to grow *in vitro* [Pratelli et al., 2003]. More recently, two CCoV-II subtypes have been recognized, namely CCoV-IIa and CCoV-IIb, on the basis on the relatedness of the spike protein of the latter virus to that of TGEV [Decaro et al., 2009, 2010b]. In addition, a virulent CCoV-IIa biotype, strain CB/05, has been proven to cause fatal infections and long-lasting lymphopenia in naturally [Buonavoglia et al., 2006; Decaro et al., 2012; Ntafis et al., 2012; Zicola

et al., 2012; Pinto et al., 2014] and experimentally [Decaro et al., 2008, 2011; Marinaro et al., 2010] infected dogs.

To date, while the CCoV-II genome has been fully determined [Decaro et al., 2015], only fragments of the 3' genomic end are available for CCoV-I. Therefore, in the present study we have carried out the complete genome sequence analysis for this canine pathogen. The results showed that the CCoV-I genome displays some distinct features with respect to CCoV-II and other alphacoronaviruses. The first finding is the presence of an additional accessory protein gene, ORF3, which was located between the S protein gene and ORF3a. This additional gene, which has been recently characterized, was found to be unique to the CCoV-I genome, whereas CCoV-II and TGEV exhibit only 5' and 3' end remnants [Lorusso et al., 2008]. However, FCoV strains harboring different forms of ORF3 and a CCoV-I N protein gene have been detected, thus proving the circulation of FCoV-I/CCoV-I recombinant viruses [Le Poder et al., 2013]. Another finding of the CCoV-I genome is that the S protein gene is closely related to that of FCoV-I, whereas the rest of the genome displays a higher relatedness to CCoV-II. In addition, a furin cleavage site leading to the potential generation of two subunits, S1 and S2, as demonstrated for beta- and gammacoronaviruses. A similar basic motif is present, approximately in the same position, in most beta- and gammacoronaviruses. Cleavage of the CoV S protein has been correlated to cell-fusion activity *in vitro* but the potential implications in viral pathobiology have not been fully determined [Hingley et al., 1998]. In addition to CCoV-I, furin cleavage motifs have been detected in FCoV-I, but even in this case the biological consequences were not completely understood [de Haan et al., 2008]. Unlike CCoV-II and FCoV-II that display a similar S protein as a consequence of homologous recombination, CCoV-I does not grow in cell cultures and only few FCoV-I strains have been adapted to grow *in vitro*. The CoV S protein interacts with cell receptors, thus being responsible for binding of virions to the cell surface [Enjuanes et al., 1991]. Thus, the different S proteins between CCoV-I/FCoV-I and CCoV-II/FCoV-II are likely to be responsible for the diverse biological behaviours in cell cultures. The cell receptor for most *Alphacoronavirus-1* isolates is the

cell surface glycoprotein aminopeptidase N (APN), but there is no evidence for this receptor being used by CCoV-I/FCoV-I [de Haan et al., 2008].

On the basis of the most recent findings, the evolutionary history of *Alphacoronavirus-1* members has been tentatively reconstructed, suggesting that CCoV-I and FCoV-I are the ancestral viruses from which TGEV, CCoV-II and FCoV-II have originated through gene losses and recombination events [Lorusso et al., 2008]. Our findings corroborate the hypothesis that CCoV-I is the ancestor for CCoV-II, since these viruses exhibit high identity in the entire genome with the exception of the S protein gene, which is markedly diverse, and ORF3, of which only remnants are present in the CCoV-II genome.

In conclusion, the full-length sequencing of the CCoV-I genome may contribute to a better understanding of the *Alphacoronavirus-1* evolutionary pattern and may be paradigmatic of how CoVs evolve through gene losses, acquisition and exchanges among different members.

1 **Figure legend**

2 **Fig. 1.** Schematic representation of the genomes of *Alphacoronavirus-1* members depicting the
3 genetic differences among the CCoV genotypes. Genes encoding for structural and non-structural
4 proteins are shown in grey and white, respectively. ORF sizes are not drawn to scale. The arrows
5 indicate the transcription regulating sequences preceding each CoV gene.

6
7 **Fig. 2. Phylogenetic analysis of CCoV-I strain 23/03 and other members of the species**

8 *Alphacoronavirus-1*. Neighbor-joining trees are based on the 23,106-nt fragment spanning from the
9 3' end of ORF3a to the very 3' end of the viral genome (A), and on the spike (B), membrane (C)
10 and nucleocapsid (N) proteins. For phylogenetic tree construction, the reference strains and
11 GenBank accession numbers are as reported in Table 3. The distantly-related *Betacoronavirus-1*
12 canine respiratory coronavirus (CRCoV) K37 (JX860640) was used as outgroup. A statistical
13 support was provided by bootstrapping over 1,000 replicates. The scale bars indicate the estimated
14 numbers of nucleotide (A) or amino acid (B-D) substitutions.

Table 1. Coding potential, putative transcription regulatory sequences and encoded proteins of the CCoV-I 23/03 genome.

Putative gene		Putative TRS		Putative protein	
Gene name	Coding sequence (nt)	Start nt position	TRS sequence*	Protein name	Protein size (aa)
ORF1ab	314-12,327 12,327-20,358	90	UCGAAC <u>UAAAC</u> GAAAU	Pp1ab	6,681
ORF1a	314-12,358			Pp1a	4,014
